Introduction	9
1 An introduction to Schatten classes	13
1.1 Compact operators	13
1.1.1 Compactness	13
1.1.2 Compact operators in Banach spaces	14
1.1.3 Compact operators in Hilbert spaces	18
1.2 Other important operator families in Hilbert spaces	19
1.2.1 Normal operators	19
1.2.2 Unitary operators	21
1.2.3 Positive operators	22
1.3 Spectral properties in Hilbert spaces	24
1.3.1 Extreme eigenvalues of compact self-adjoint operator	25
1.3.2 Diagonalization of finite-dimensional matrices	25
1.3.3 Diagonalization of compact self-adjoint operators	26
1.4 Singular value decomposition	27
1.4.1 Finite-dimensional case of Singular Value Decomposition	27
1.4.2 Singular Value Decomposition for compact operators in Hilbert spaces	27
1.5 Schatten classes $S^p \subset \mathcal{K}(H)$	29
2 Interpolation spaces	35
2.1 Two classical results	35
2.1.1 The Riesz-Thorin Interpolation Theorem	35
2.1.2 The Marcinkiewicz Interpolation Theorem	37

2.2	Lorentz spaces	41
2.2.1	Decreasing rearrangement	41
2.2.2	Definition and basic properties of the Lorentz spaces	45
2.2.3	The Lorentz sequence spaces and the Schatten Lorentz classes	49
2.3	General Properties of Interpolation Spaces	50
2.3.1	Categories and functors	50
2.3.2	Quasi-Normed Abelian Groups and Normed Vector Spaces	51
2.3.3	Couples of Spaces	54
2.3.4	Definition of Interpolation Spaces	55
2.4	The Real Interpolation Method	58
2.4.1	The K -method	59
2.4.2	The J -Method and the Equivalence Theorem	67
2.4.3	The Reiteration Theorem and the Power Theorem	69
2.5	Interpolation of L^p -spaces and Lorentz spaces with the real method	72
2.6	Approximation of functions and operators, and applications to interpolation theory	80
2.6.1	Approximation spaces	80
2.6.2	Approximation of Functions	103
2.6.3	Approximation of Operators	107
2.6.4	Application to interpolation of Schatten classes	113
3	Singular Integral Operators: some general results and a focus on Hilbert Transforms associated with various curves	125
3.1	Homogeneous Singular Integral Operators of Convolution Type	125
3.2	The Hilbert Transform on the line	132
3.2.1	Definition and main properties	132
3.2.2	Connection with holomorphic functions	136
3.3	The Hilbert Transform on the circle	151
3.3.1	Definition of the Hilbert transform, the Poisson kernel for the circle, and its conjugate	151
3.3.2	The Herglotz integral and its normal limits	154
3.3.3	Comparison between the Hilbert transform on the line and on the circle	174

3.3.4	Appendix: the Schwarz formula	176
3.4	The Hilbert Transform on Lipschitz curves	182
3.4.1	Definition and L^2 -Boundedness	183
3.4.2	Connection with holomorphic functions: the Plemelj formulae	190
4	Schatten classes and commutators of singular integral operators	193
4.1	Some Preliminary Definitions and References	193
4.2	Statement of the main result	205
4.3	Proof of sufficiency in Theorem 4.2.1	205
4.3.1	Proof of Theorem 4.3.1	206
4.3.2	Proof of Theorem 4.3.2	206
4.4	Proof of necessity in Theorem 4.2.1: the case $p > n$	214
4.4.1	Proof of Theorem 4.4.1	215
	Bibliography	247
	Acknowledgements	249

Introduction

As suggested by the title, this thesis covers various areas in mathematical analysis: it contains foundational topics in operator theory, interpolation spaces, and singular integrals, which provide a comprehensive framework for understanding the advanced results in the article by S. Janson and T. H. Wolff [14]. The contents of this significant work are discussed in Chapter 4. Below, I will summarize the contents of this thesis in greater detail.

The first Chapter aims to introduce the so-called Schatten classes, which are specific classes of compact operators on Hilbert spaces characterized by the fundamental property that the sequence of their singular values belongs to a certain ℓ^p space. To achieve this, several foundational topics are presented first, including compact operators with some of their basic properties, other classes of operators (normal, unitary, positive), the concept of diagonalization for compact self-adjoint operators, and finally the singular value decomposition of a compact operator on Hilbert spaces.

Chapter 2, on the other hand, aims to provide the foundational knowledge on interpolation spaces necessary for understanding the article [14]. Its contents are mainly drawn from the book [3]. In particular, after introducing the Riesz-Thorin theorem and the Marcinkiewicz theorem, two classical results, a general discussion of interpolation space theory is presented, with a specific focus on the Real Method. Subsequently, the specific case of interpolation using the Real Method for Lorentz spaces $L^{p,q}$ and Schatten-Lorentz classes $S^{p,q}$ is illustrated, where Lebesgue spaces L^p and Schatten classes S^p respectively appear as special cases.

The third Chapter of this work pursues multiple goals. The first is to provide the theoretical foundations for homogeneous singular integral operators of convolution type, so as to give context to the discussion in Chapter 4 about the article [14]. To this end, Section 3.1 presents sufficient conditions for these operators to be bounded from L^p to

L^p , for $1 < p < \infty$, and from L^1 to $L^{1,\infty}$. Two classic examples, the Hilbert and Riesz transforms, are also mentioned.

After stating these general results, the remainder of Chapter 3 focuses on the Hilbert transform in its various forms: on the line, on the circle, and on an arbitrary Lipschitz curve. This part was motivated by an interest in exploring this topic for its own sake, rather than as auxiliary results.

Sections 3.2 and 3.3 are developed in parallel to one another, to better highlight similarities and differences between the Hilbert transform on the line and that on the circle. A nearly identical analogy is that both are bounded from L^p to L^p for $1 < p < \infty$, and from L^1 to $L^{1,\infty}$. Moreover, in both cases, there exists an integral operator that, under suitable assumptions on the (real valued) function f to which it is applied, has as its real part the convolution of f with the Poisson kernel and as its imaginary part the convolution of f with the so-called conjugate Poisson kernel. Additionally, under appropriate assumptions, it is possible to show that such an integral converges to $f + iHf$ on the boundary, where for brevity we use the same notation H to denote the Hilbert transform on the line and on the circle. What sets the two situations (line and circle) apart from one another, however, are primarily the required assumptions on f , which differ in the two cases, as well as the integrals that are involved: twice the Cauchy integral for the line and the Herglotz integral for the circle.

In Section 3.4, the Hilbert transform on an arbitrary Lipschitz curve is discussed. The study of this case is particularly interesting because, unlike the cases of smoother curves, it cannot be reduced to the example of a straight line or a circle, thus requiring new techniques.

In Subsection 3.4.1, after introducing its definition, we give some glimpses of the proof of the L^2 -boundedness of the Hilbert transform on Lipschitz curves, as presented in the important paper [7] by R. Coifman, A. McIntosh, and Y. Meyer. This work, published in 1982, improves upon an earlier, highly significant result by A. P. Calderón [4] from 1977, where the L^2 -boundedness of the Hilbert transform on Lipschitz curves was proven, though with the restriction that the Lipschitz constant of the curve must be sufficiently small.

In Subsection 3.4.2, a property known as the *Plemelj formulae* is stated, which in some sense generalizes the case of the real line for the boundary values of Cauchy-type integrals.

The results presented in Chapter 3 are, for simplicity, all discussed in the specific case of \mathbb{R}^n , equipped with the n -dimensional Lebesgue measure, and with the $(n - 1)$ -dimensional Hausdorff measure in the case of surfaces. However, many of these results also hold for more general spaces and measures.

Finally, as mentioned at the beginning of this introduction, Chapter 4 contains a detailed presentation of the work in [14]. The main result proven in this paper is as follows. Suppose that T is a homogeneous singular integral operator of convolution type with kernel $K \in C^\infty(\mathbb{R}^n \setminus \{0\})$, and, if $f \in L^1_{\text{loc}}(\mathbb{R}^n)$, denote by M_f the pointwise multiplication by f . Consider the commutator $C_f = M_f T - T M_f$. Then, necessary and sufficient conditions for $C_f \in S^p$ are that f belongs to an appropriate Besov space if $p > n$, or that f is constant if $0 < p \leq n$.

In Section 4.3, the proof of sufficiency is presented. Particularly noteworthy is the proof that, in the case $p > n$, if f belongs to an appropriate Besov space, then C_f is in the Schatten class S^p . This proof utilizes a result concerning mixed norm spaces $L^p(L^q)$ and several results from interpolation space theory. Moreover, while following the general structure of the proof in [14], the version presented here includes some slight differences: the version proposed in this thesis does not require knowledge of results related to interpolation of Besov spaces using the real method.

In Section 4.4, the proof of the reverse implication for the case $p > n$ is presented: if C_f belongs to the Schatten class S^p , then f belongs to a specific Besov space. This proof is highly technical, and its core idea is to estimate the mean oscillation, first over single dyadic cubes and then by averaging over all dyadic partitions of \mathbb{R}^n . Through this approach, the condition for f to belong to the desired Besov space is obtained.
